### Description

The iVENCS Network module is a comprehensive network monitoring package that is fully integrated into the iVENCS Control System.

Operating as a subsystem within the core server and workstation software, iVENCS Network Monitoring provides operators with current and historical status updates on the control system's IP network. The module offers a complete view of the site's IP equipment, network, server, and workstation processes, simplifying installation and maintenance tasks for the iVENCS Control System and IP networked subsystem equipment. The system is scalable and can efficiently monitor a large number of devices, ensuring the health and performance of even the largest systems without excessive server or network bandwidth usage.
